What do you have to know to call a function?

- Function's name
- What header file must be included?
- List of parameters, if any. For each:
    - What type is it?
    - Value or Reference?
        - For Value, corresponding argument can be any value (variable, literal, constant, expression, etc.) of that type or convertible to that type
        - For Reference, corresponding argument must be a variable (something that lives in memory) of the exact type
- Return type, if any.
    - If function returns a value, you probably want to capture/use/acknowledge it in some manner.

```
retType funcName ( type param1, type param2, … , type paramn );

        retType variable = funcName ( arg1, arg2, … , argn );
```
